CHEMICAL RESISTANCE OF PTFE

Chemical: Organic and halogenated solvents

Effect: Swell, reversible after short-term exposure, irreversible after long-term exposure

Chemical: Alkali metals, in solution or molten state

Effect: Elimination of fluorine, destruction of the polymer

Chemical: Halogens, gaseous fluorine, chlorine trifluoride, oxygen difluoride

Effect: Chemical reactions possible at elevated temperatures, destruction of the polymer, swelling, explosion possible

Chemical: Monomers: Such as styrene, butadiene and acrylonitrile

Effect: Penetration possible, spontaneous polymerization may destroy the polymer

Chemical: Concentrated sodium and potassium hydroxide

Effect: Temperature > 200° C, Chemical reaction possible

Chemical: Strong Lewis bases (boranes, aluminium chloride, ammonia, some amines and imines)

Effect: Temperature close to 260° C, Chemical reaction can occur at high temperature close or above maximal service temperature

Chemical: 70 % nitric acid

Effect: Temperature ≥ 250° C under pressure, Slow oxidative attack possible

Chemical: High energy radiation

Effect: Gamma radiation: 10 kGy dosage may already reduce physical properties by approximately 50%

Chemical: Nitrating acid: Mixture of conc. H_2SO_4 and HNO_3

Effect: Temperature >100° C, Decomposition of the fluoropolymer possible
